## 1. Introduction

The EMEP Centre on Emission Inventories and Projections (CEIP) operates the UNECE/EMEP emission database (WebDab) which contains information on air pollutant emissions and projections from the Parties to the Convention on Long-Range Transboundary Air Pollution (LRTAP) (UNECE 1979). Furthermore, emissions used in EMEP models (gap-filled emissions) and gridded emissions in Google maps are synthesized and made available on the CEIP website ([www.ceip.at](http://www.ceip.at), CEIP 2022).

Data processed by CEIP were reported by the Parties to the LRTAP Convention as sectoral emissions (NFR14) and National Total emissions according to the UNECE guidelines for reporting emissions and projections data under the LRTAP Convention, Annex I (UNECE 2014). For gap-filling and gridding by CEIP, the NFR14 sector data are aggregated to 13 GNFR sectors. In several cases, no data were submitted by the countries, or the reporting is not complete or contains errors. Before these emission data can be used by modelers, missing/erroneous information have to be filled in/replaced. To gap-fill/replace emissions data, CEIP applies a systematic quality control and gap-filling routine. After gap-filling is complete, the territorial sector emissions are then mapped spatially using the EMEP grid system.

This documentation describes how the reported emissions of main pollutants ( $\text{NO}_x$ , NMVOCs,  $\text{SO}_x$ ,  $\text{NH}_3$ ), CO, particulate matter ( $\text{PM}_{2.5}$ ,  $\text{PM}_{10}$  and  $\text{PM}_{\text{coarse}}$ ) and black carbon (BC) are subject to a central quality control and, where necessary, how these data are gap-filled/replaced. The document also explains how emissions from other regions in the EMEP domain, which are not obliged to report emissions data, are incorporated. In 2020, CEIP updated and streamlined procedures. The reasons for undertaking this step were: 1) the need to incorporate new independent estimates; and 2) the ever-increasing number of years for which the reported data need to be evaluated and processed. The same procedures were applied in 2021; however, QA/QC and gap-filling procedures that were previously dependent on the v4.3.2 EDGAR dataset (Crippa et al., 2018) have been updated and now use the v5.0 EDGAR dataset instead (Crippa et al., 2019).

## 2. Summary of the of the quality control and gap-filling process

The first step is to collect and synthesize the official submissions by the Parties to the LRTAP Convention. All submissions received **up to 7<sup>th</sup> April 2022** were used as a basis for the gap-filled data set. Parties report their emissions inventories to the LRTAP Convention as sectoral emissions (NFR14) and National Total emissions according to the UNECE guidelines for reporting emissions and projections data under the LRTAP Convention, Annex I (UNECE 2014). The reported NFR sector emissions are then aggregated to the 13 GNFR sectors used for the gridding procedure (A cross-walk between the NFR and aggregated GNFR sectors is provided in Annex II, Table A 2):

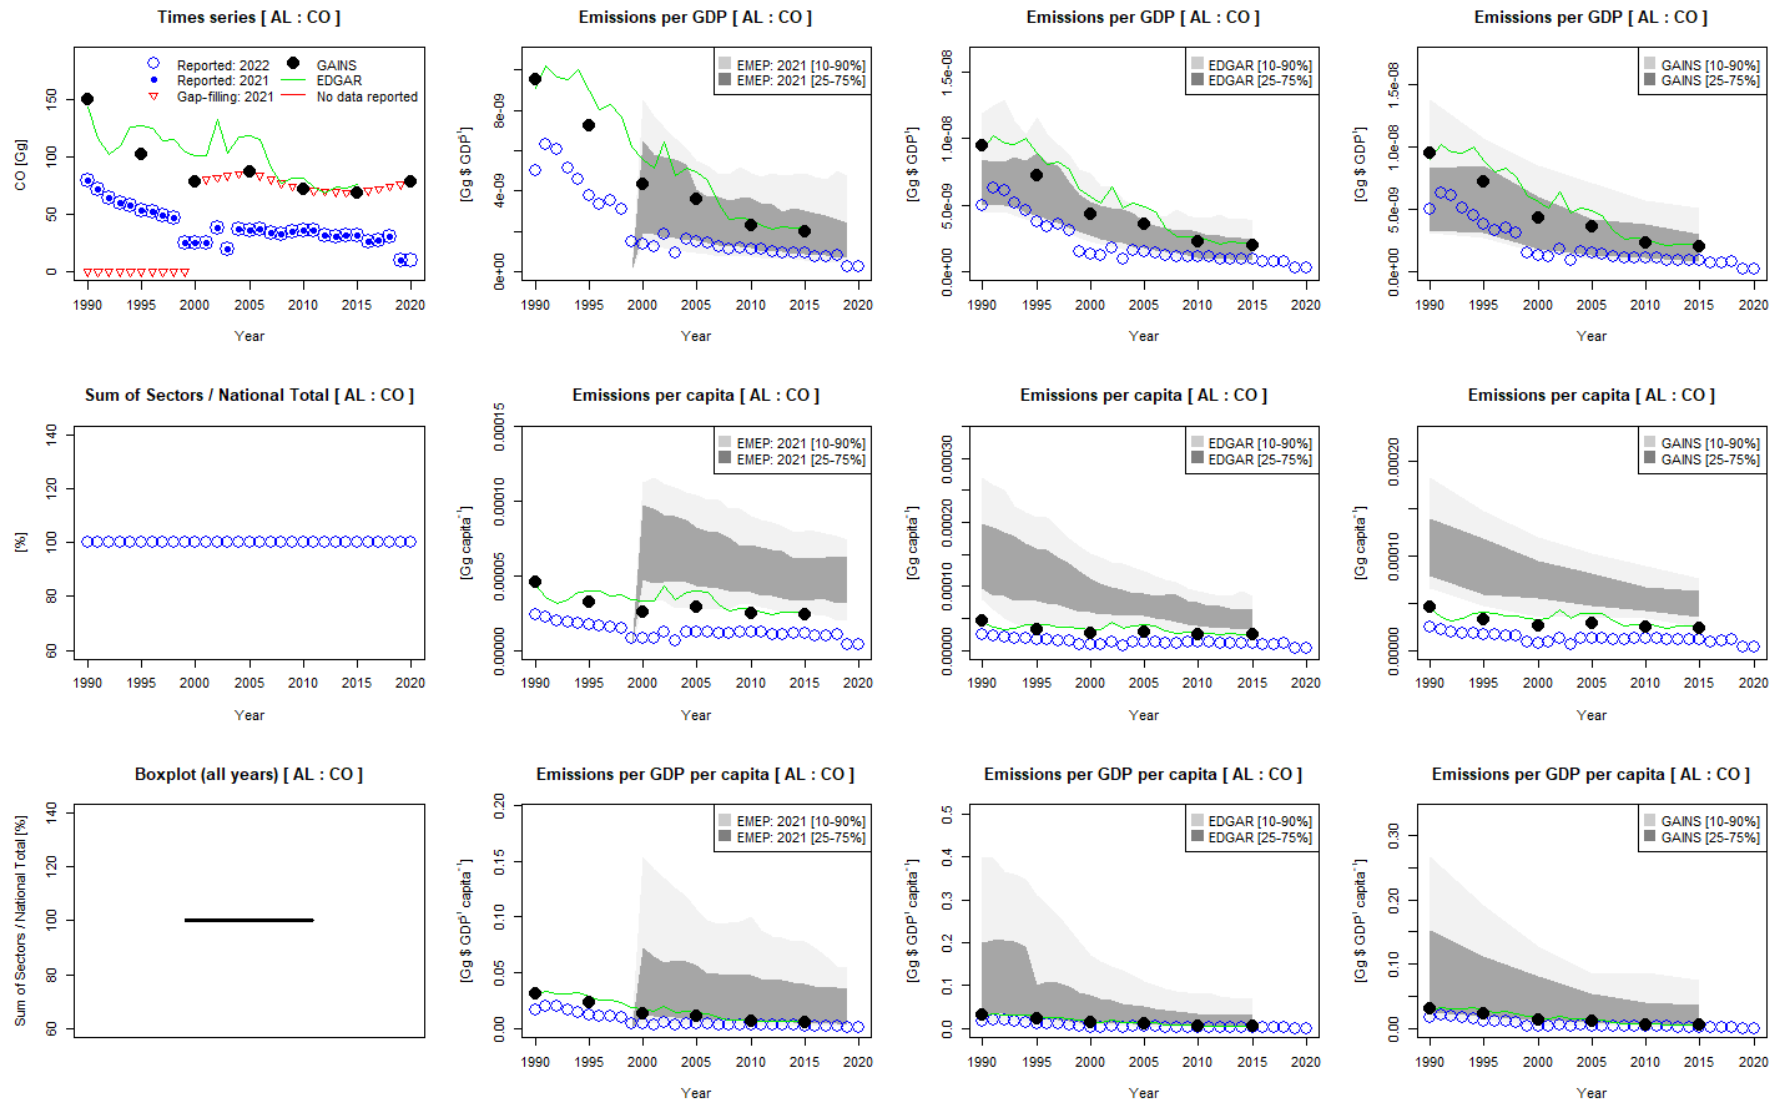

1. A\_PublicPower
2. B\_Industry
3. C\_OtherStationaryComb
4. D\_Fugitive
5. E\_Solvents
6. F\_RoadTransport
7. G\_Shipping
8. H\_Aviation
9. I\_Offroad
10. J\_Waste
11. K\_AgriLivestock
12. L\_AgriOther
13. M\_Other

The dataset of reported emissions is then checked to ascertain where data are missing and to evaluate the plausibility of those emissions estimates which are reported. To do this a routine, coded in the open source statistical programming environment, R<sup>1</sup>, retrieves the current dataset of reported emissions and processes these data with other datasets (previously reported and gap-filled EMEP datasets, independent emissions datasets and data on economic indices). For each pollutant of each country, quality control graphs are generated, with which assigned experts can evaluate the plausibility of the reported emissions.

a)

b)

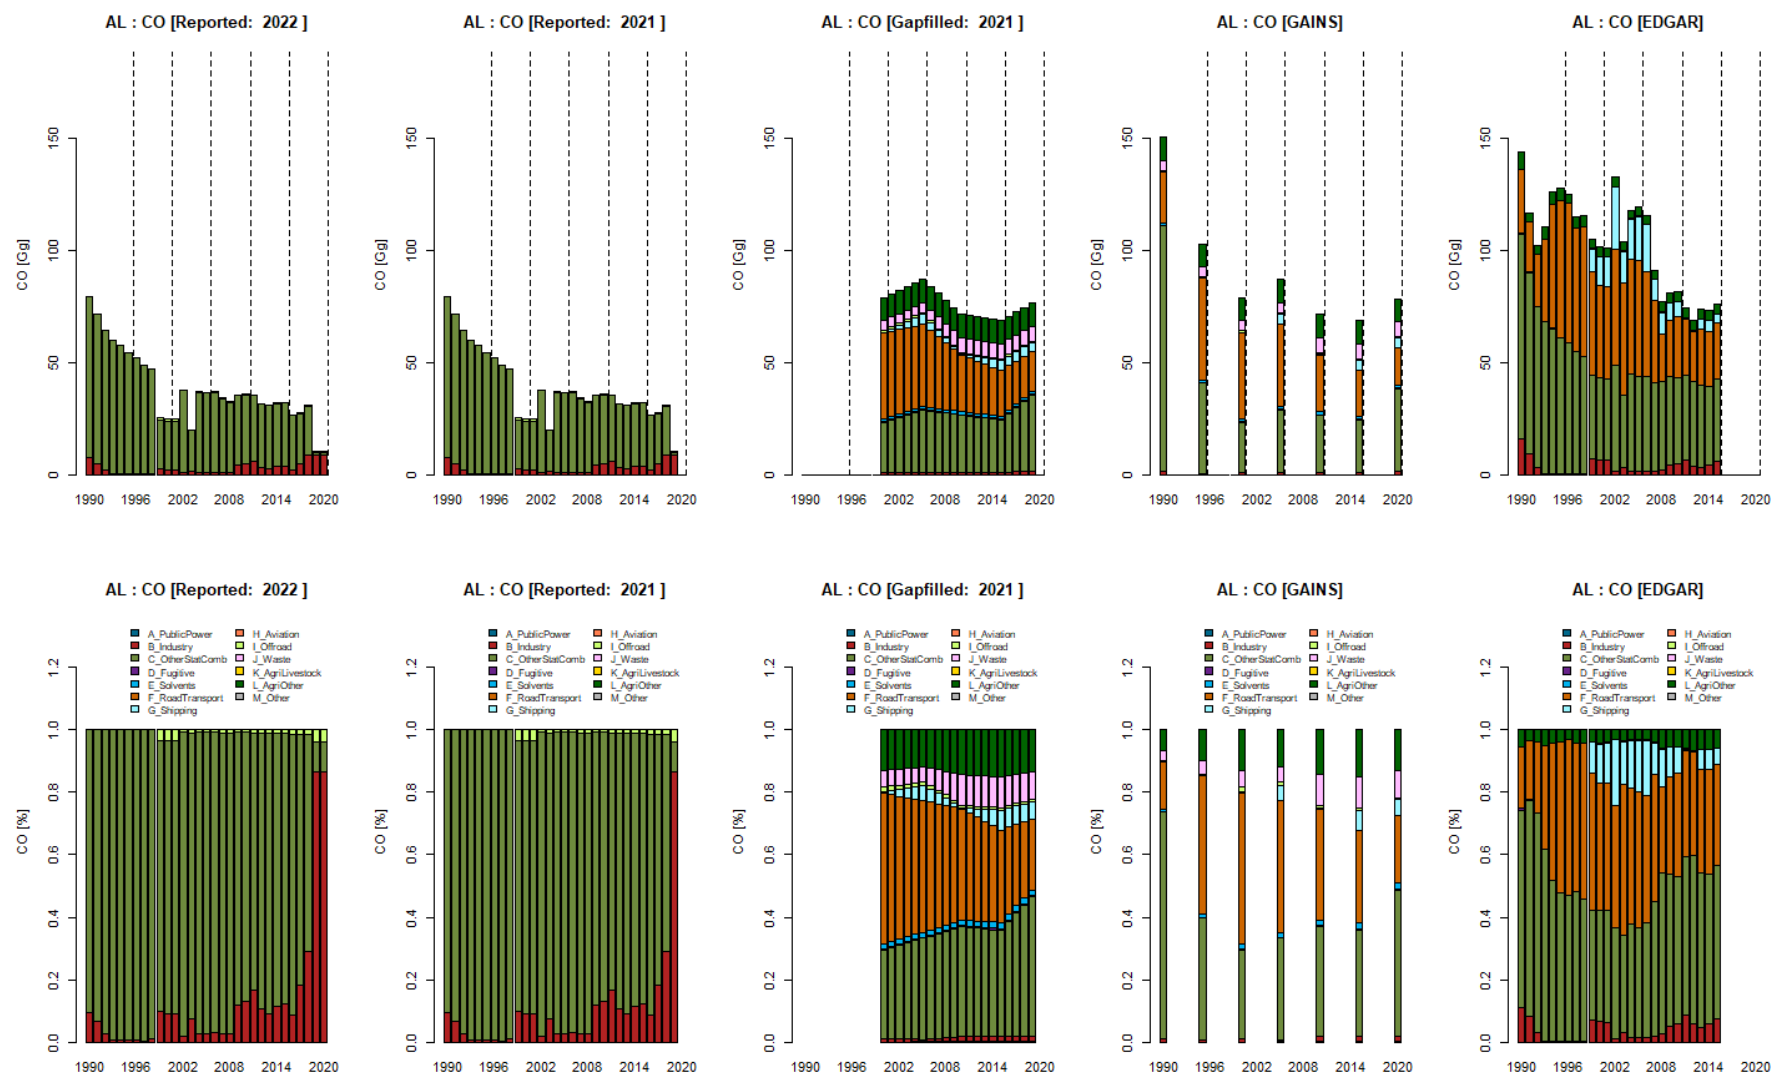

Figure 1: Quality control graphs for evaluating the plausibility of Albania's reported CO emissions both at the national total (a) and GNFR sector (b) level.

As the example for Albania's CO emissions (Figure 1a) demonstrates, the time series of the reported national totals are compared against the same emissions reported in the previous year, as well as the time series contained within the gap-filled EMEP dataset of the previous year. For comparison, respective national totals from independent sources are also plotted. The independent datasets used are the v5.0 EDGAR dataset<sup>2</sup> (1970-2015, Crippa et al. (2019)) and the latest v6b ECLIPSE dataset<sup>3</sup> (1990, 1995, 2000, 2005, 2010, 2015 and 2020 projection) from the Greenhouse gas – Air pollution Interactions and Synergies model, GAINS (Amann et al., 2011). Below this graph of the time series of national total emissions, a scatterplot and boxplot illustrate whether the sum of sector emissions added up to the reported national totals. Finally, the national total time series is normalized against economic statistics from the World Bank<sup>4</sup> and plotted against respective ranges as calculated from the previously gap-filled EMEP dataset and from the EDGAR and GAINS datasets.

In addition to these graphs at the national total level, corresponding quality control graphs are generated to evaluate the reported sectoral emissions. As Figure 1b demonstrates, the sectoral emissions and relative distributions are compared against those reported and gap-filled in the previous year and against respective values from the EDGAR and GAINS datasets.

Such graphs are generated for all the main pollutants, as well as for PM<sub>2.5</sub>, PM<sub>10</sub> and BC. However, for the particulate emissions, additional mass balance assessment graphs are also generated (Figure 2).

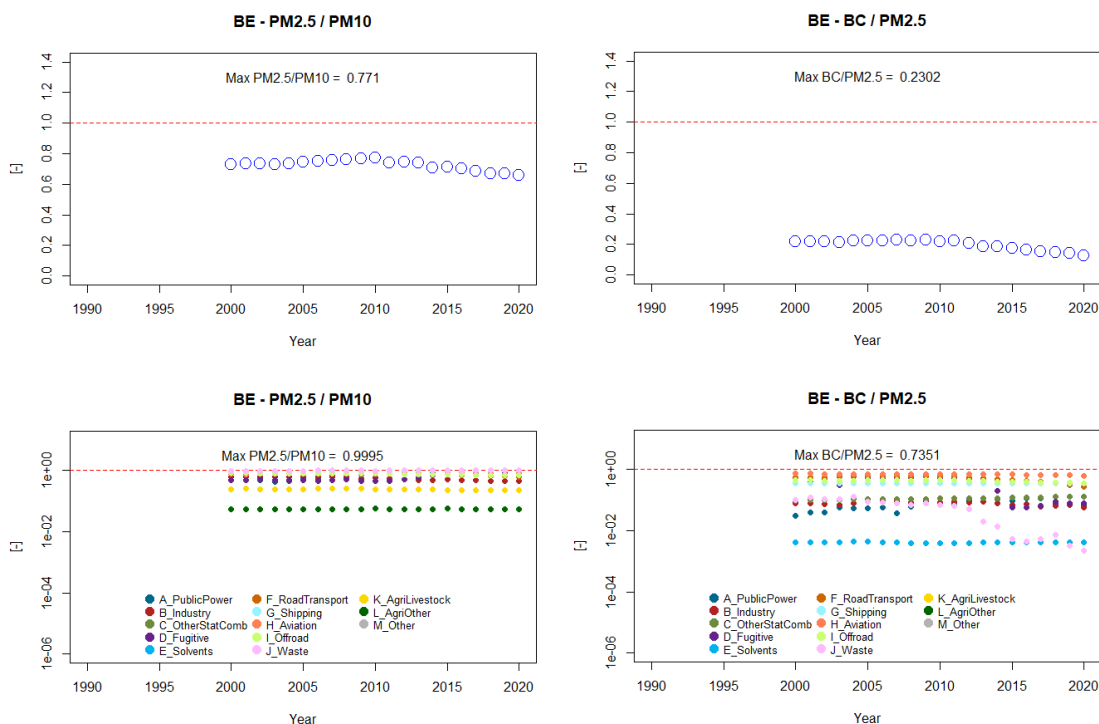

Figure 2: Mass balance evaluation of Belgium's particulate matter emissions (PM<sub>2.5</sub>, PM<sub>10</sub> and BC)

<sup>4</sup> <http://datatopics.worldbank.org/world-development-indicators/>

Based on the generated quality control graphs, CEIP experts check for where data are missing and importantly whether the reported emissions are plausible. Where data from 1990 onwards are missing and/or implausible, CEIP experts must select the most appropriate gap-filling/replacement option from a set of predefined methods:

- *Replacement* – where no data are available or no plausible data are available, the most appropriate option is to replace the time series with the respective estimates from the interpolated GAINS ECLIPSE v6b dataset. This option can be applied to either all GNFR sectors (Figure 3) or in certain cases to a single GNFR sector (Figure 4).

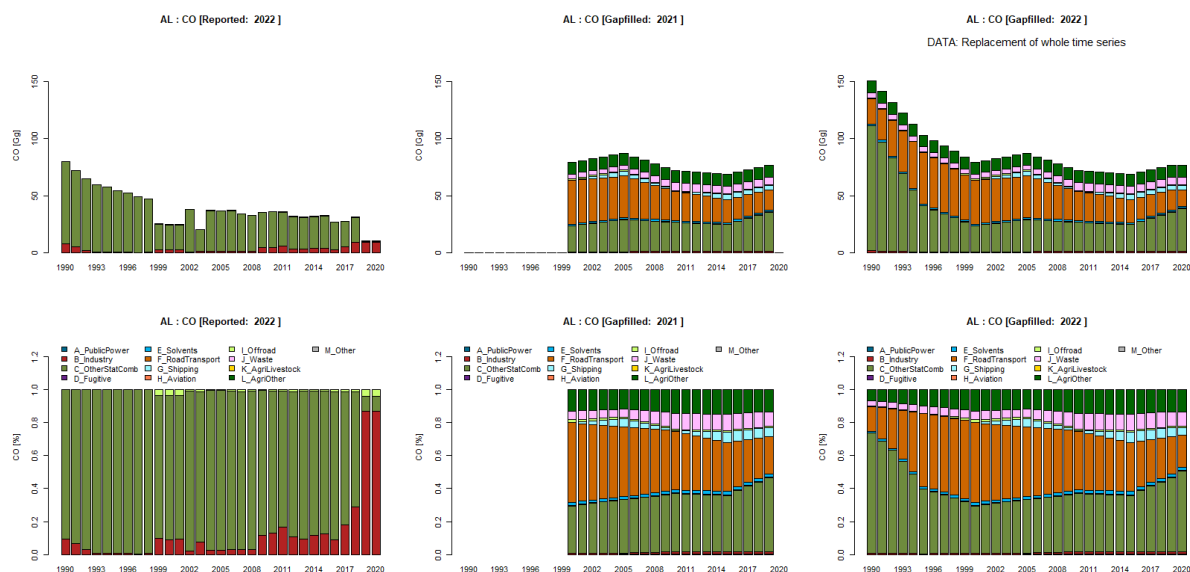

Figure 3: Example of *Replacement* of all sectors (Albania, CO)

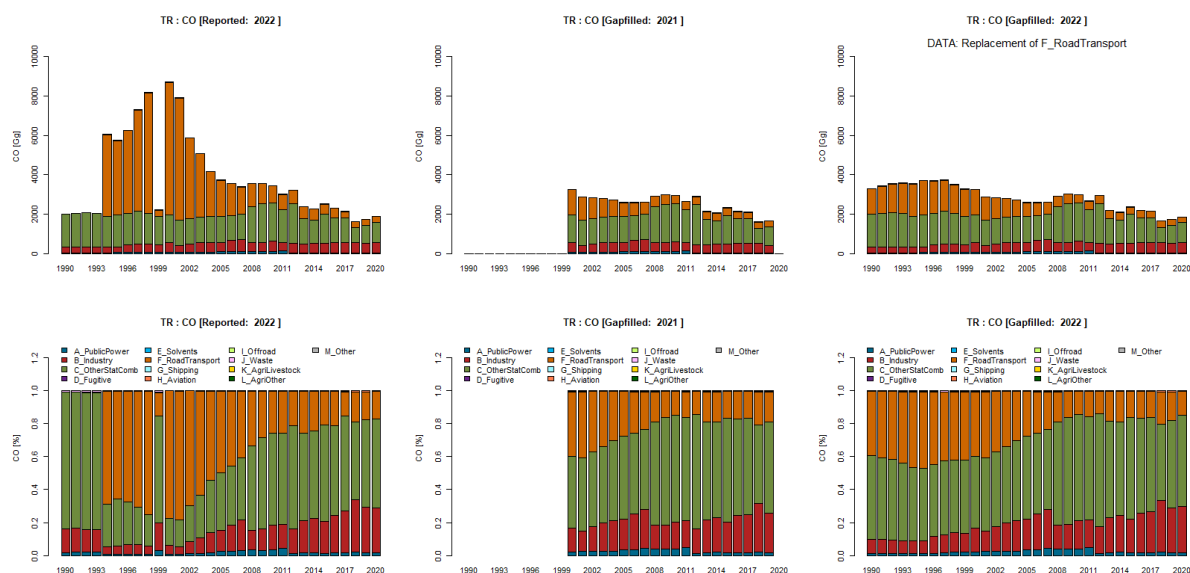

Figure 4: Example of *Replacement* of a single sector (Turkey, CO)

- *Extrapolation* - where a significant portion of the data appears plausible, it is appropriate to extrapolate the missing/implausible years at the beginning and/or end of the time series. In this case the expert must decide the trend with which to extrapolate the national total:

- Constant emissions are assumed (Figure 5); or
- Using the respective trends from GAINS estimates or even reported national totals (where national totals seem plausible), or a mix of both (Figure 6)

Like *Replacement*, this option can be applied to single sector or all sectors. In the case that all sectors are extrapolated, the national total is in fact extrapolated, and subsequently split between sectors based on a sector split of the nearest year deemed plausible.

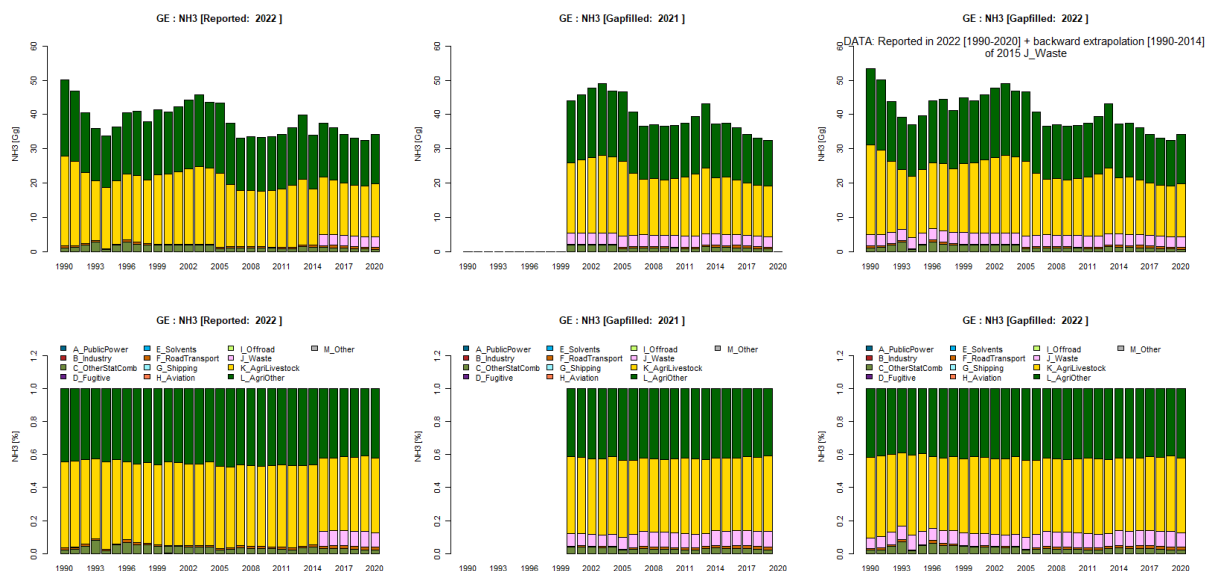

Figure 5: Example of Extrapolation (Georgia, NH<sub>3</sub> – waste emissions from 2015 extrapolated backwards assuming emissions were constant)

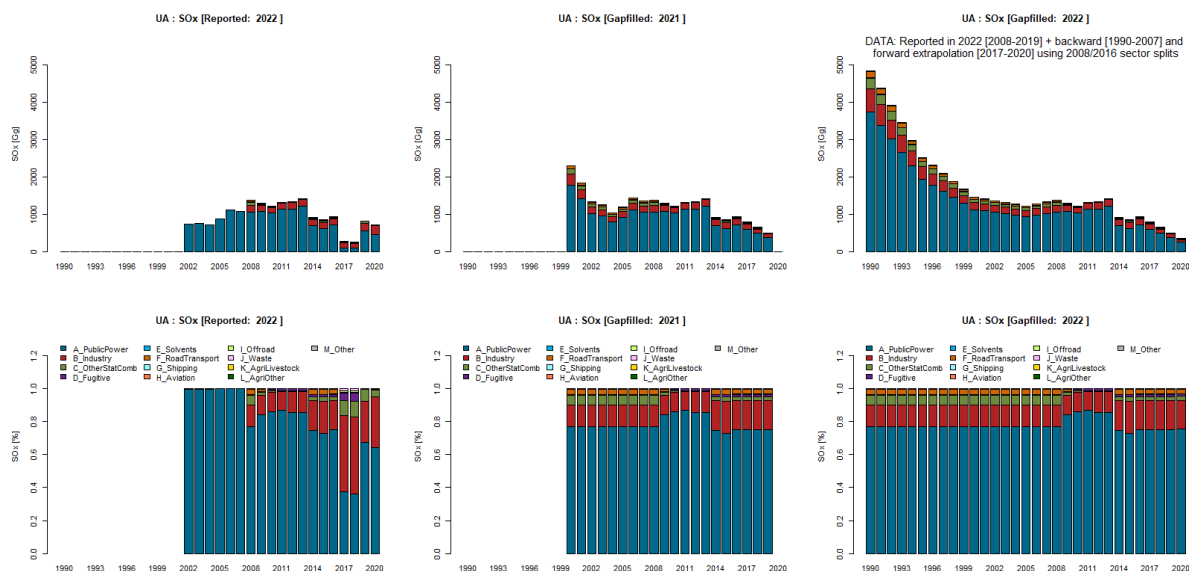

Figure 6: Example of multi-year Extrapolation (Ukraine, SO<sub>x</sub>). The backward extrapolation was based on trends in reported national totals whereas the forward extrapolation was based trends in national totals according to GAINS.

- *Ratio* – where the PM<sub>2.5</sub> emissions are plausible, yet BC has not been reported or appears implausible, this option is considered the most appropriate. For this option, the reported sector PM<sub>2.5</sub> emissions are multiplied by BC fractions (GNFR sector-specific) derived from

respective GAINS estimates of PM<sub>2.5</sub> and BC emissions. In most cases, the ratios from the respective country are taken (Figure 7); however, for small countries which are not resolved by GAINS, another country's BC fractions can be selected (Figure 8). Again this option can be applied to either all sectors or a single sector if e.g. there is mass balance issue for the said GNFR sector.

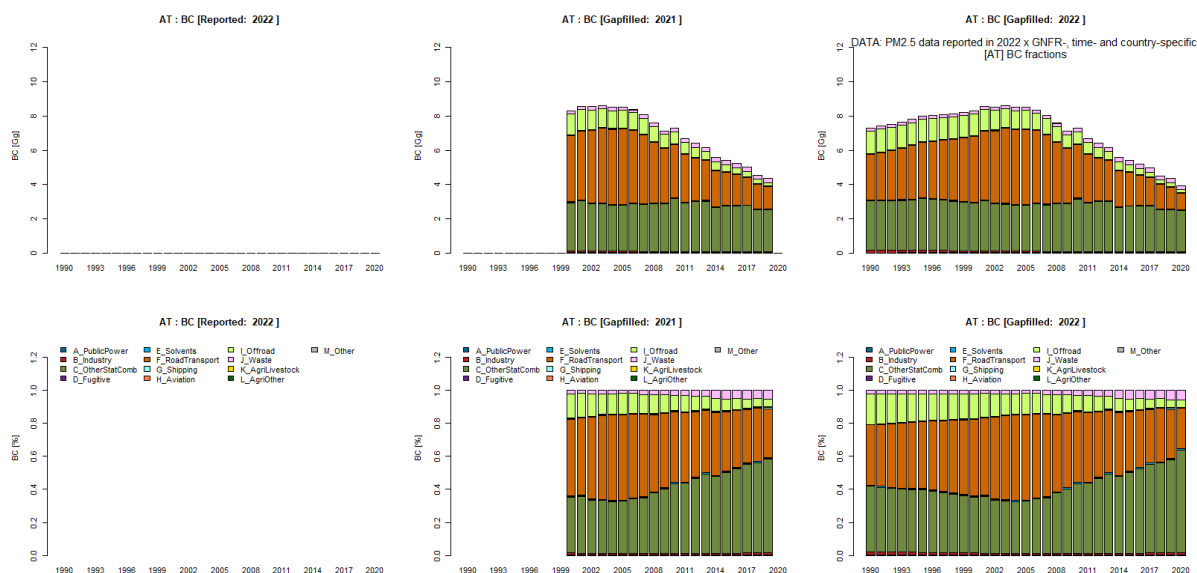

Figure 7: Example of BC gap-filling using reported PM<sub>2.5</sub> emissions and BC fractions from GAINS (Austria)

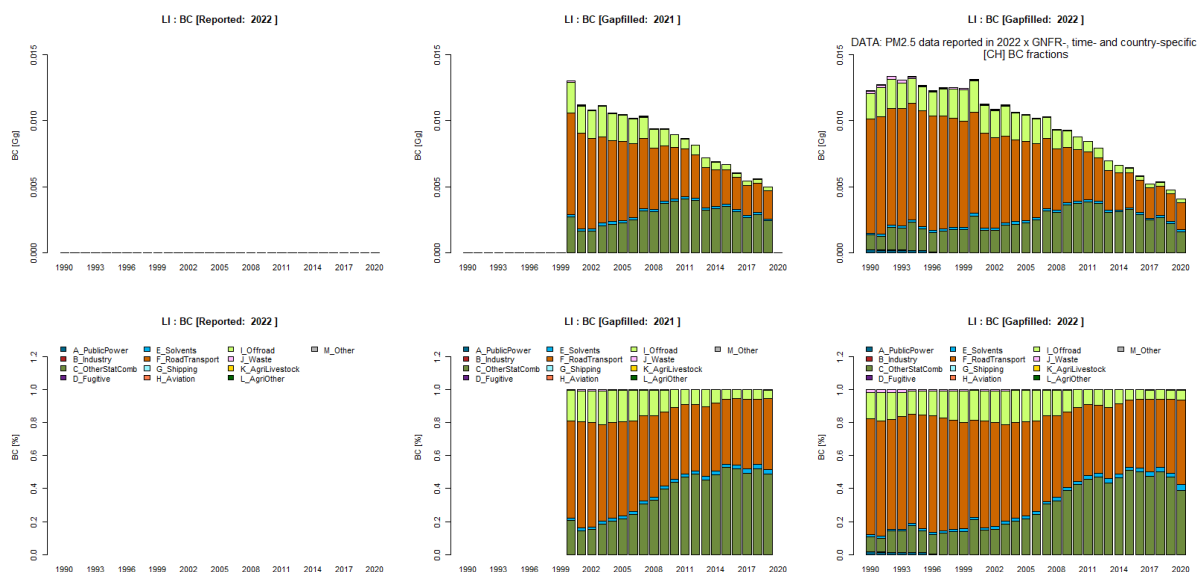

Figure 8: Example of BC gap-filling using reported PM<sub>2.5</sub> emissions and BC fractions from GAINS but from another Country (Liechtenstein using the GAINS BC fractions from Switzerland)

- *Interpolation* – this option can be applied on its own (Figure 9) or in combination with the extrapolation methods. In this case, missing/improbable emissions for years in between periods of plausible data are simply replaced by linear interpolation.

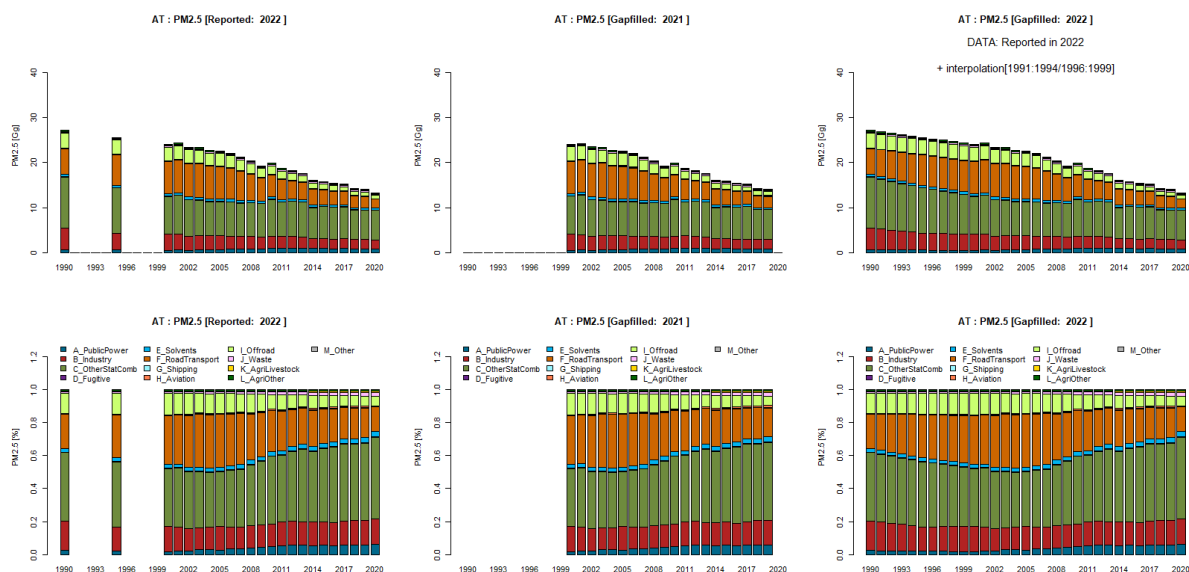

Figure 9: Example where additional interpolation was required (Austria, PM<sub>2.5</sub>)

CEIP experts thus work through a spreadsheet survey summarising the plausibility of the reported emissions, noting missing data and selecting the most appropriate gap-filling option (Figure 10). Once this spreadsheet is complete, a subsequent R routine reads these instructions and implements the gap-filling procedures thus generating a complete EMEP dataset to be gridded.

Before the dataset is finalised, the routine finally corrects for any residual errors (e.g. rounding errors) by replacing all national totals with the respective sum of totals. Any instances where sectoral emissions of PM<sub>2.5</sub> > PM<sub>10</sub> are corrected by replacing the PM<sub>10</sub> emissions with corresponding PM<sub>2.5</sub> emissions. Coupled to this step, the routine calculates the emissions of coarse particulate matter (PM<sub>coarse</sub>) by subtracting sectoral PM<sub>2.5</sub> emissions from the corresponding PM<sub>10</sub> emissions.

**Due to the COVID-19 pandemic, the gap-filling process was refined to take into account the impacts of lockdown measures on 2020 emissions.** Where 2020 emissions of all- or single sectors were replaced/gap-filled with the 2020 projection of GAINS (a projection which of course represented a business-as-usual (BAU) scenario), the emission value was corrected using pollutant- and GNFR –specific adjustment factors calculated by Guevara et al. (2022). The authors of this paper kindly provided the data to CEIP as pollutant- and GNFR –specific adjustment factors representing changes in pollutant emissions relative to country-specific BAU scenarios. The data were compiled for the CAMS European regional emission inventory dataset (CAMS-REG\_v5.1), which is geographically similar to the EMEP grid. While the adjustment factors were compiled at the country, pollutant and GNFR level, not all country, pollutant and GNFR level combinations required for the EMEP dataset are represented. Therefore the selection and application of an adjustment factor followed a hierarchical approach, using the country-, pollutant- and GNFR-specific factor, if available. If the respective factor was not available, a regional (e.g. EU, EECCA, West Balkans) or domain-wide mean adjustment factor for the pollutant and GNFR sector was calculated from the respective countries for which factors were available. As factors for BC were not compiled by Guevara et al. (2022), respective PM<sub>2.5</sub> adjustment factors were applied to the gap-filled/replaced BC emissions for 2020.

Figure 10: Screenshot of the quality control evaluation- and gap-filling instruction spreadsheet from 2020.

### 3. Gap-filling 2022

Table A lists all the pollutants and countries for which gap-filling/replacement was required. The Table also details which methods were applied to complete/replace the respective time series.

In addition to this summary, further supplementary documentation of the 2022 quality control and gap-filling is attached to this document as a zip folder containing:

- All quality control graphs for each pollutant of each reporting EMEP country
- The complete spreadsheet survey documenting the expert judgement of plausibility and the selection of the gap-filling methods for each pollutant of each reporting EMEP country
- Output graphs for each pollutant of each reporting EMEP country plotting reported emissions together with the same emissions, gap-filled or replaced emissions which were incorporated into the final EMEP dataset.

Table A: List of Parties and pollutants requiring gap-filling, replacement or interpolation and the methods applied.

| CC | Country                | Component | Gapfilling / Replacement required | Method                      | Start     | End       | Sectors | Extrapolation trend | Split     | Ratio | Interpolation required | Interpolation years |

## 4. Data availability and gap-filling method for other regions

For a number of regions in the EMEP domain, emissions are not reported because the countries are not Party to the Convention and/or because only part of their respective territories are included within the EMEP grid. Almost all these emissions are also processed as part of the R routine, where the data are sourced and filled as described below. The emissions from international shipping are however filled as part of separate, subsequent step.

### 4.1. Russian Federation in the extended EMEP domain (RUE)

The partially gap-filled emissions reported by Russia (RU) are estimates for the Russian territory west of the Urals. This however does not cover the complete part of the Russian territory which is within the extended EMEP domain (RUE). The emissions of NO<sub>x</sub>, NMVOCs, SO<sub>x</sub>, NH<sub>3</sub>, CO, PM<sub>2.5</sub> and PM<sub>10</sub> from the rest of the Russian Federation in the extended EMEP domain (RUE) were estimated by interpolating between sectoral grid emissions for the area as taken from EDGAR v5.0 for 1990, 1995, 2000, 2005, 2010 and 2015. The emissions from 2016 onwards were extrapolated based on the respective relative trends of reported national total emissions for RU. Emissions of BC were estimated by multiplying the gap-filled PM<sub>2.5</sub> emissions by the GNFR sector-specific BC fractions as calculated from the GAINS estimates of Russian PM<sub>2.5</sub> and BC emissions.

### 4.2. Tajikistan (TJ), Turkmenistan (TM) and Uzbekistan (UZ)

Neither Tajikistan, Turkmenistan nor Uzbekistan are Party to the Convention and thus do not report national air pollutant emissions inventories. The emissions from these countries are estimated using the estimates from GAINS ECLIPSE v6b. The dataset provides aggregate regional estimates for area *Former USSR (Asia)*, which incorporates Tajikistan, Turkmenistan and Uzbekistan. The emissions for each country are thus estimated by dividing these aggregate regional emissions based on splits derived from national totals of these countries according to the EDGAR dataset. To maintain mass balance of the particulate emissions, PM<sub>10</sub>, PM<sub>2.5</sub> and BC are distributed between the countries based on the relative PM<sub>10</sub> split in EDGAR.

### 4.3. Sea regions: Atlantic Ocean (ATL), Baltic Sea (BAS), Black Sea (BLS), Caspian Sea (CAS), Mediterranean Sea (MED), North Sea (NOS)

Emissions from 2014 to 2020 for the sea regions were extracted from FMI (Finish Meteorological Institute) shipping data for the CAMS-GLOB-SHIP v3.1 dataset (FMI 2021).

The trend from CAMS-GLOB-SHIP v2.1 dataset was taken to calculate emissions for the earlier years, 2000 to 2013, based on v3.1 data for 2014.

Shipping emissions from 1990 to 1999 were calculated using ship emissions for 2000 adjusted with trends for global shipping from EDGAR v.5.0

Emissions of BC were estimated by multiplying the gap-filled PM<sub>2.5</sub> emissions by average GNFR sector-specific BC fractions as calculated from the GAINS estimates.

### Caspian Sea

For the Caspian Sea, FMI shipping data (FMI 2017) for 2015 were used and extrapolated based on the GDP trend of Kazakhstan.

Emissions of BC were estimated by multiplying the gap-filled PM<sub>2.5</sub> emissions by average GNFR sector-specific BC fractions as calculated from the GAINS estimates.

#### **4.4. Aral Lake (AR)**

Emissions for this area are no longer estimated separately and are now instead contained with the estimates for Kazakhstan and Uzbekistan.

#### **4.5. Remaining Asian Areas in the EMEP domain (AST)**

To calculate emissions for the remaining Asian Areas in the EMEP domain, inter- and extrapolated estimates were derived from the sectoral gridded data from EDGAR v5.0 for the years 1990, 1995, 2000, 2005, 2010 and 2015. The emissions from 2016 onwards were extrapolated based on the respective relative trends in the GDP of China. Emissions of BC were estimated by multiplying the gap-filled PM<sub>2.5</sub> emissions by average GNFR sector-specific BC fractions as calculated from the GAINS estimates.

#### **4.6. North Africa (NOA)**

To calculate emissions for North Africa region with the EMEP domain, inter- and extrapolated estimates were derived from the sectoral gridded data from EDGAR v5.0 for the years 1990, 1995, 2000, 2005, 2010 and 2015. The emissions from 2016 onwards were extrapolated based on the respective relative trends in the GDP of Morocco. Emissions of BC were estimated by multiplying the gap-filled PM<sub>2.5</sub> emissions by average GNFR sector-specific BC fractions as calculated from the GAINS estimates.
